Machine learning task!

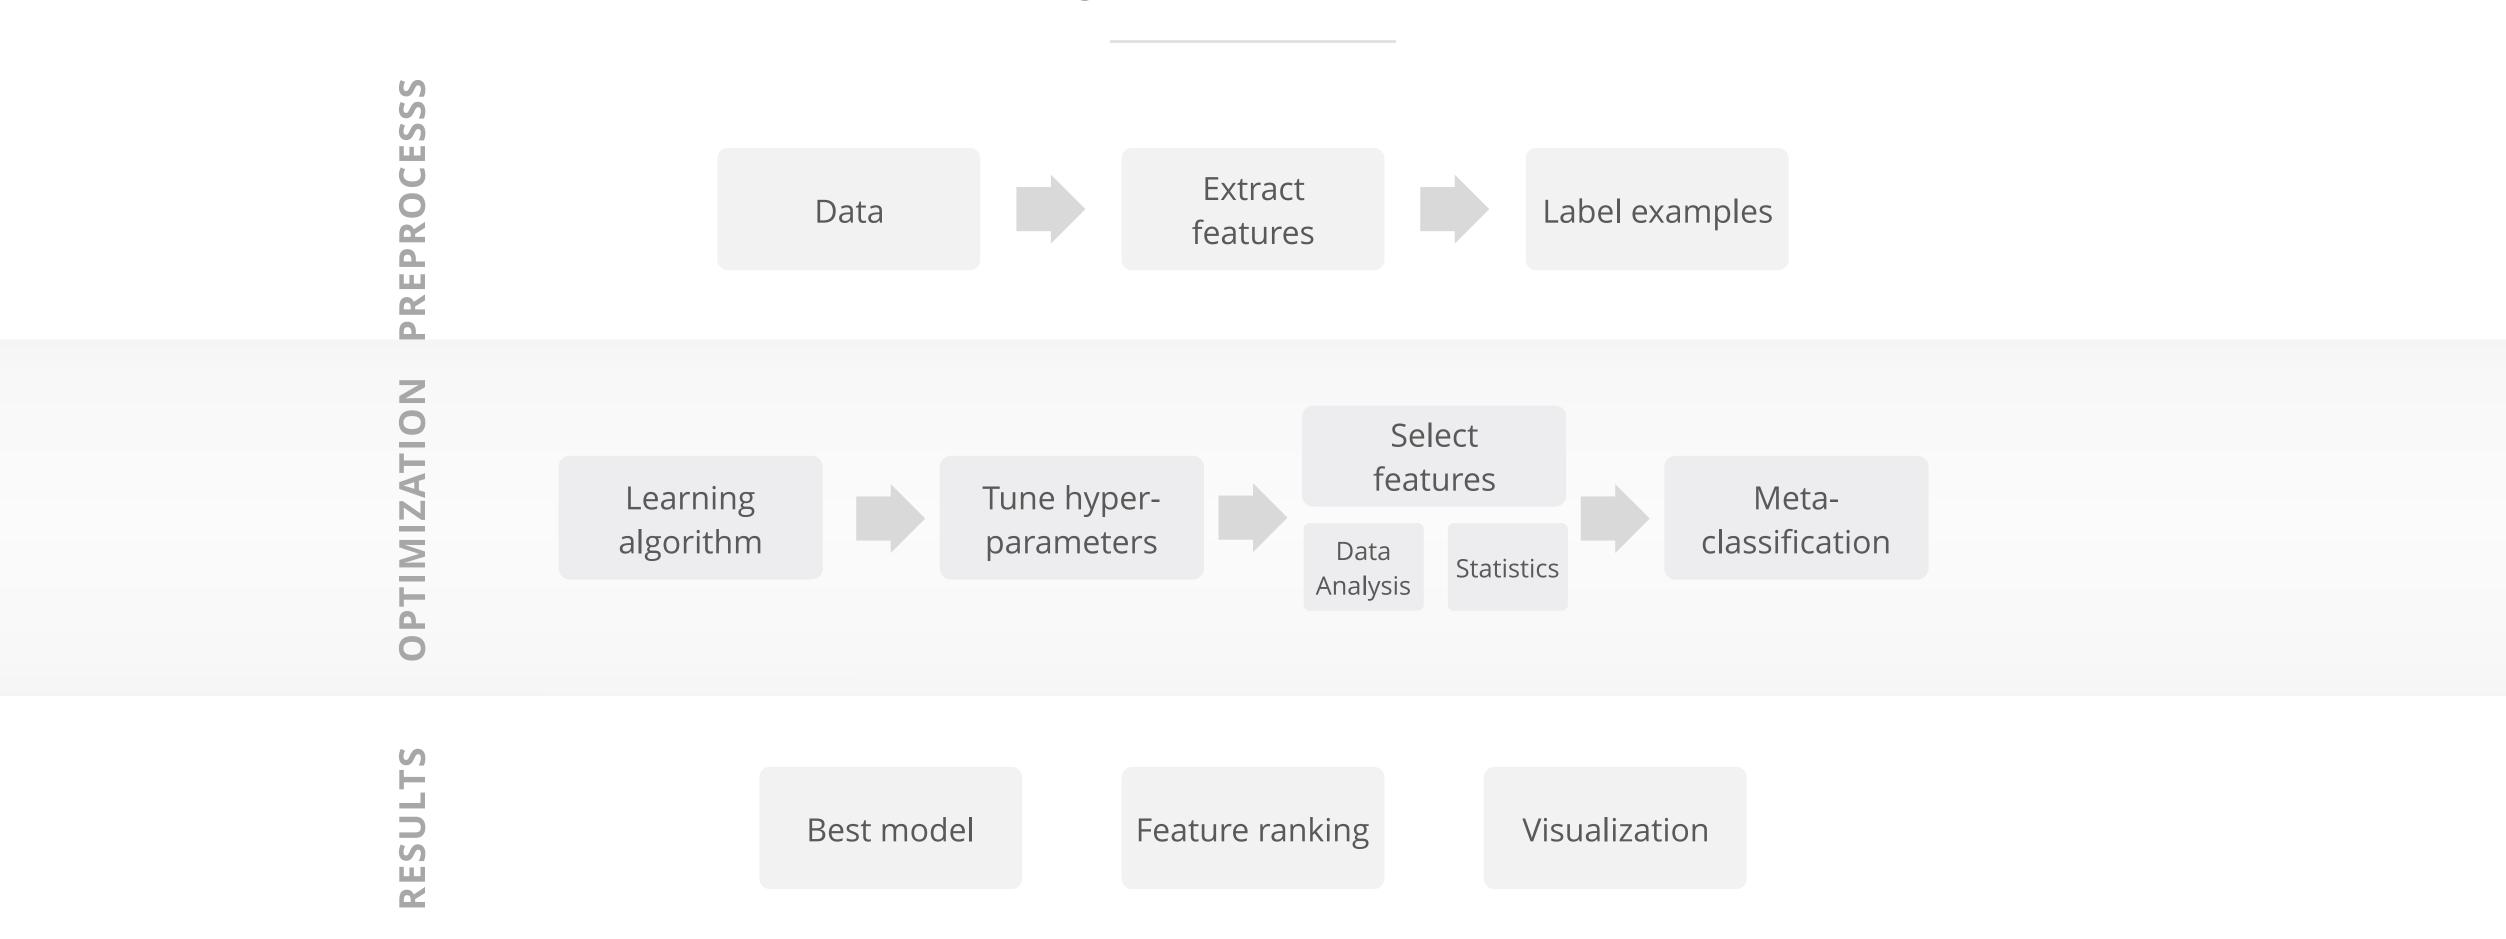

MACHINE LEARNING

train on some labeled examples, then predict label for a new example

OUR PROBLEM

given a big dataset, find most discriminatory features

OVERVIEW

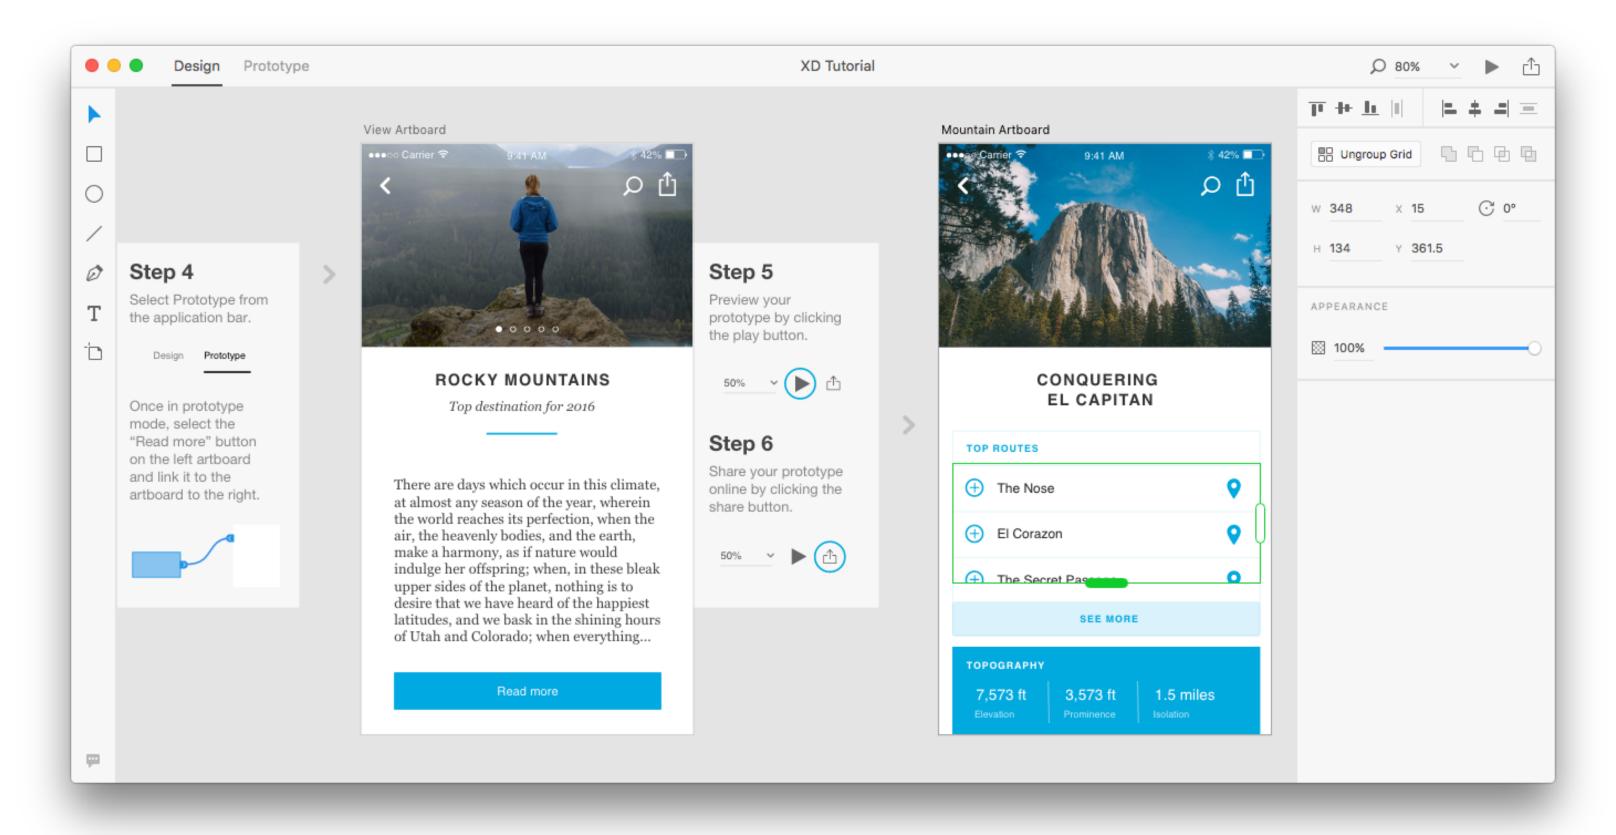

APPROACH

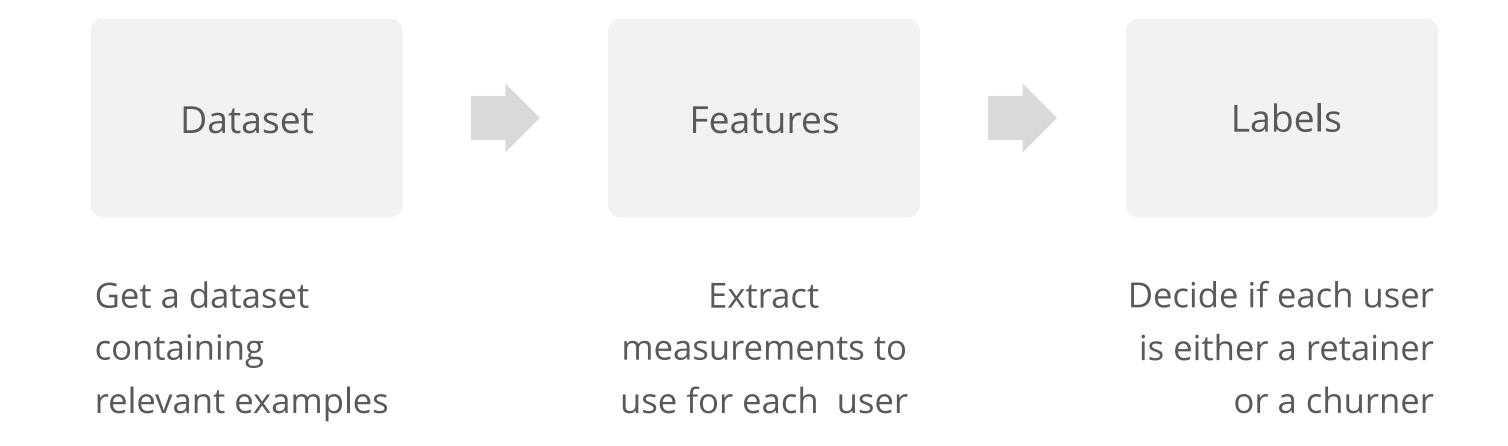

train a model,
it will understand data relationships.
ask it what features helped decide the most

more accurate model, more valuable its opinion

THE APPLICATION

BEFORE LEARNING

QUICK NUMBERS

users

sessions

43k 115k 4.8m events

no outliers (98 quantile) or accidents (<15s)

EXTRACTED FEATURES

DOCUMENT

opened, created, saved imported, exported, shared

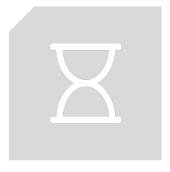

DRAWS

rectangles, ellipses, lines, paths, text artboards, repeat-grids, wires

HISTORICAL

total time, number of launches, days span

TIMES

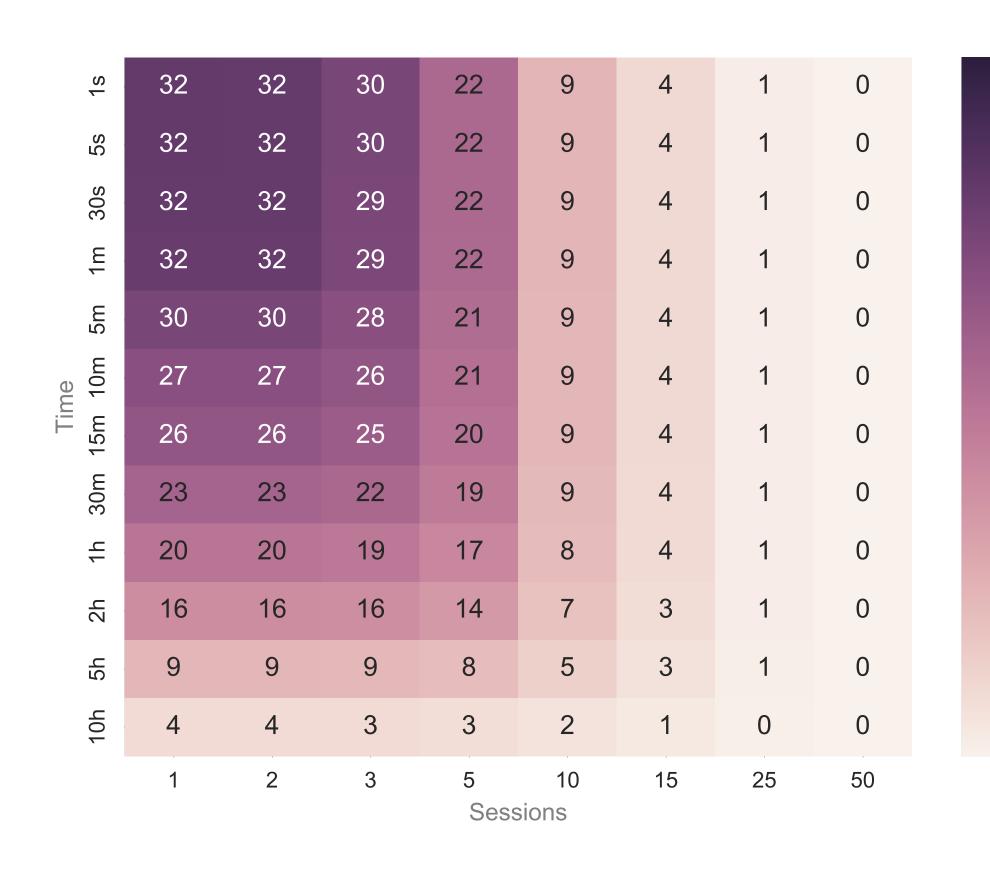

in design, prototype, preview, first session, action frequency

Counts ignore sequentiality.

Build action sequences

RETENTION DEFINITION

- time
- sessions
- days span

32%

24%

16%

8%

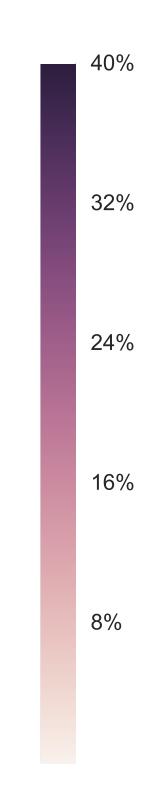

RETENTION DEFINITION

• time: 10m

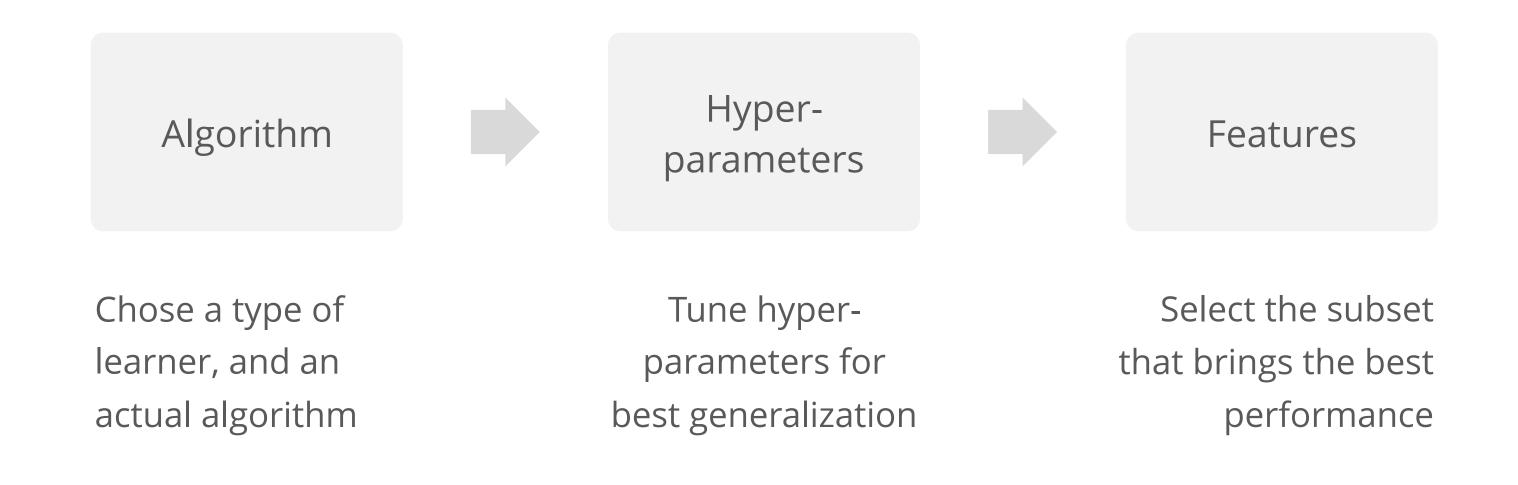

• sessions: 3

• days span: 15

2	32	32	30	22	9	4	1	0

OPTIMIZE LEARNING

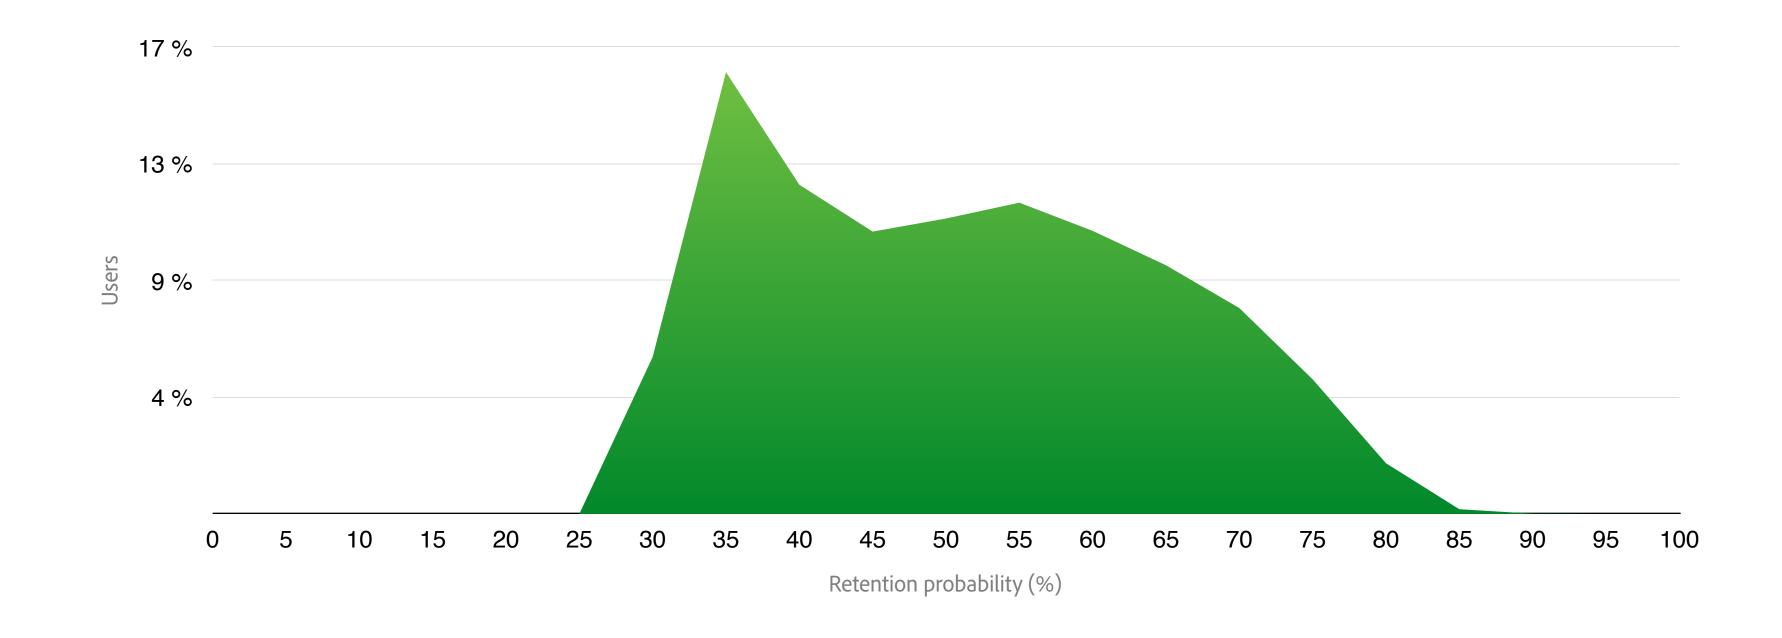

SELECTING A MODEL

- have to know the data beforehand
- need experience to pick,
- even experts need to rely on trial-and-error

PARETO IN PRACTICE

RETENTION DISTRIBUTION

LEARNING ALGORITHMS

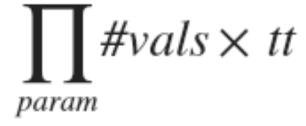

- neural networks
- support vector machines
- decision tree forests
- naive bayes
- logistic regression
- gradient descent

- boosting
- bagging

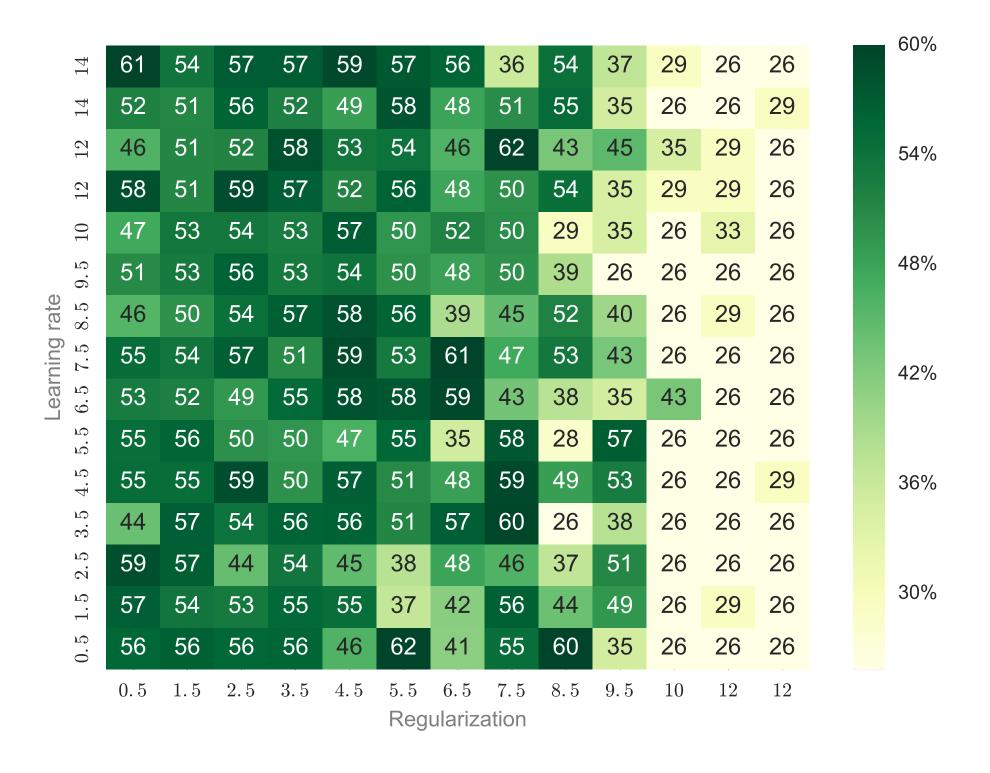

No free lunch theorem

HYPER-PARAMETERS

- models need to be tuned to be effective
- many have multiple hyper-parameters
- can't try every possible combination

HYPER-PARAMETER GRID

Horizon effect

HYPER-PARAM SEARCH

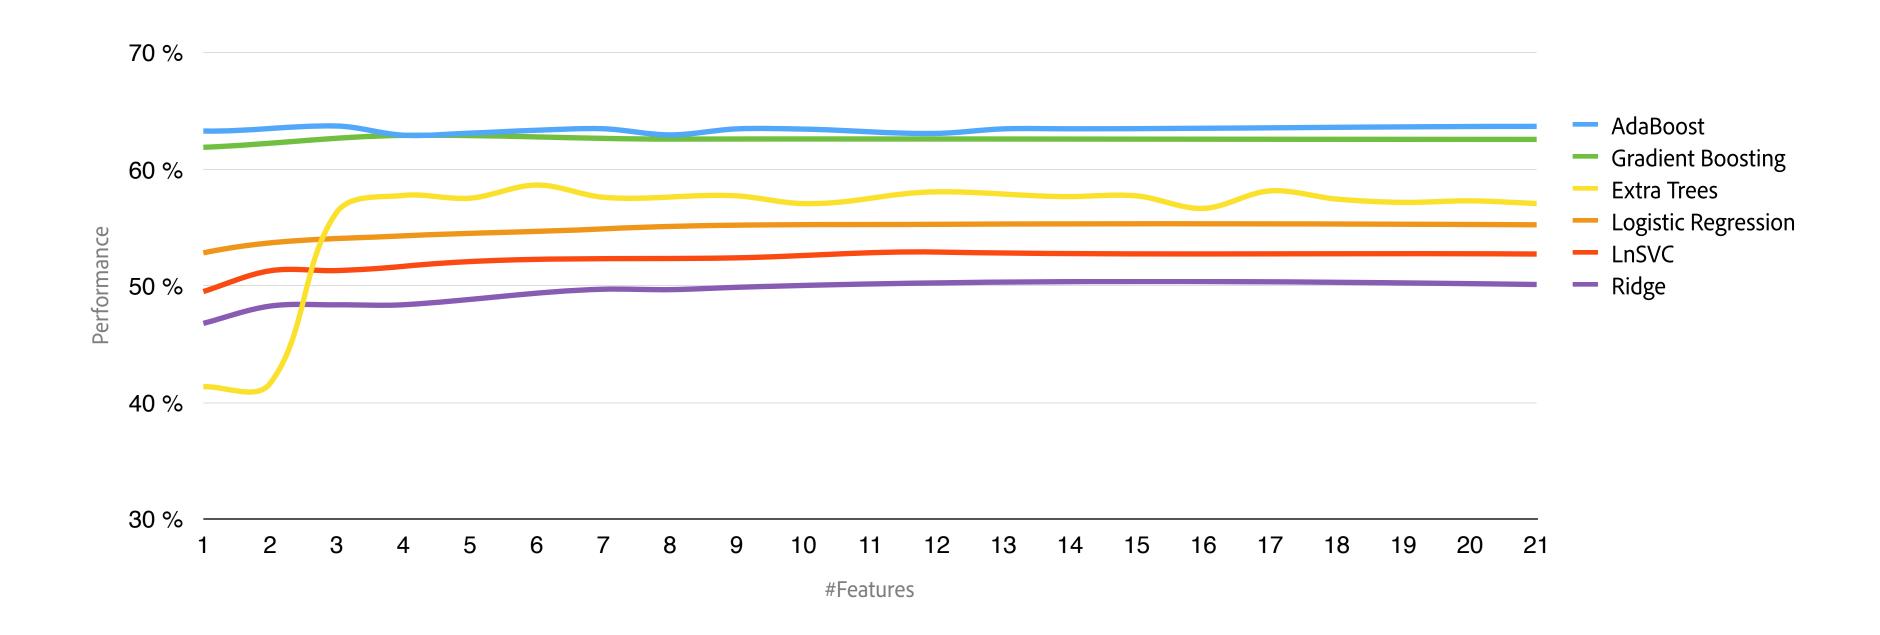

- grid search when model is fast
- randomized search instead
- and for continuous distributions as well

FEATURE SELECTION

- reduces complexity
- easier to interpret
- will learn relationships, not noise
- requires smaller training set

Curse of dimensionality

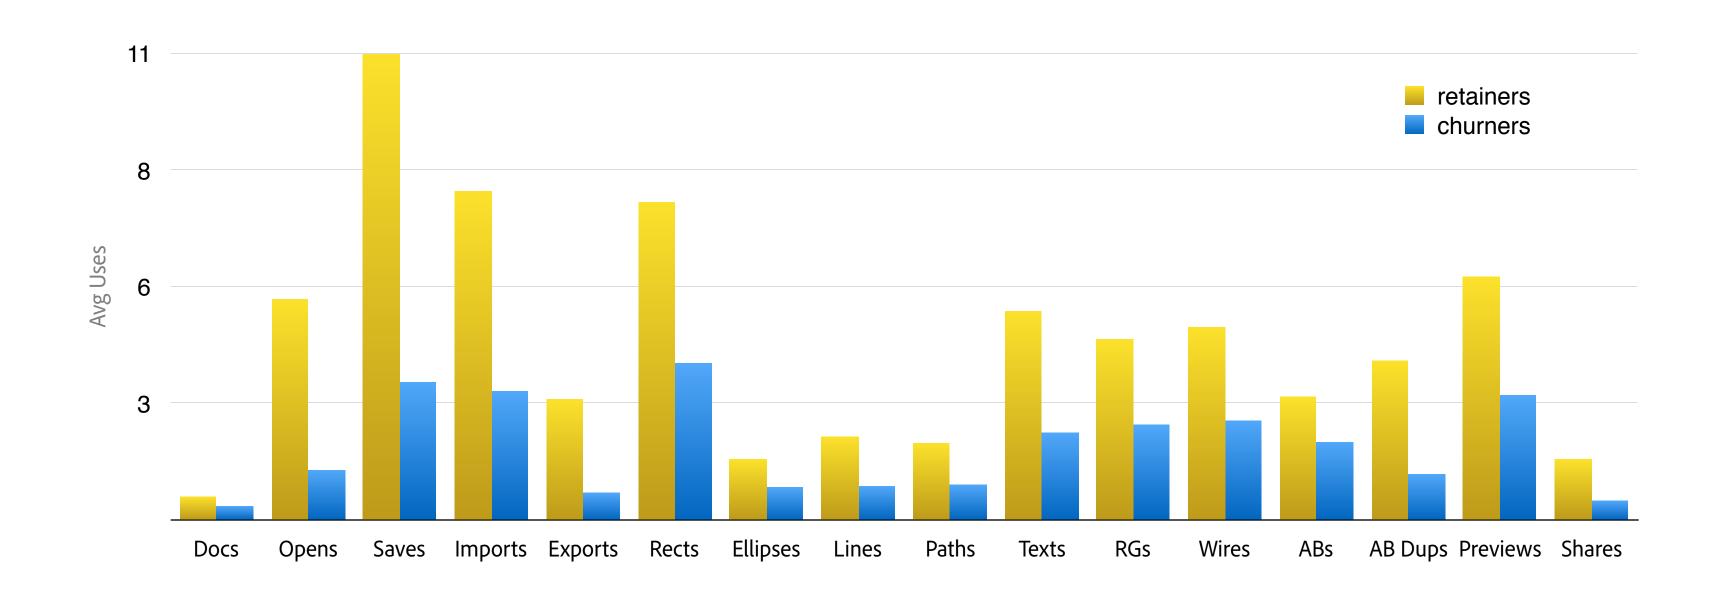

SUBSET PERFORMANCE

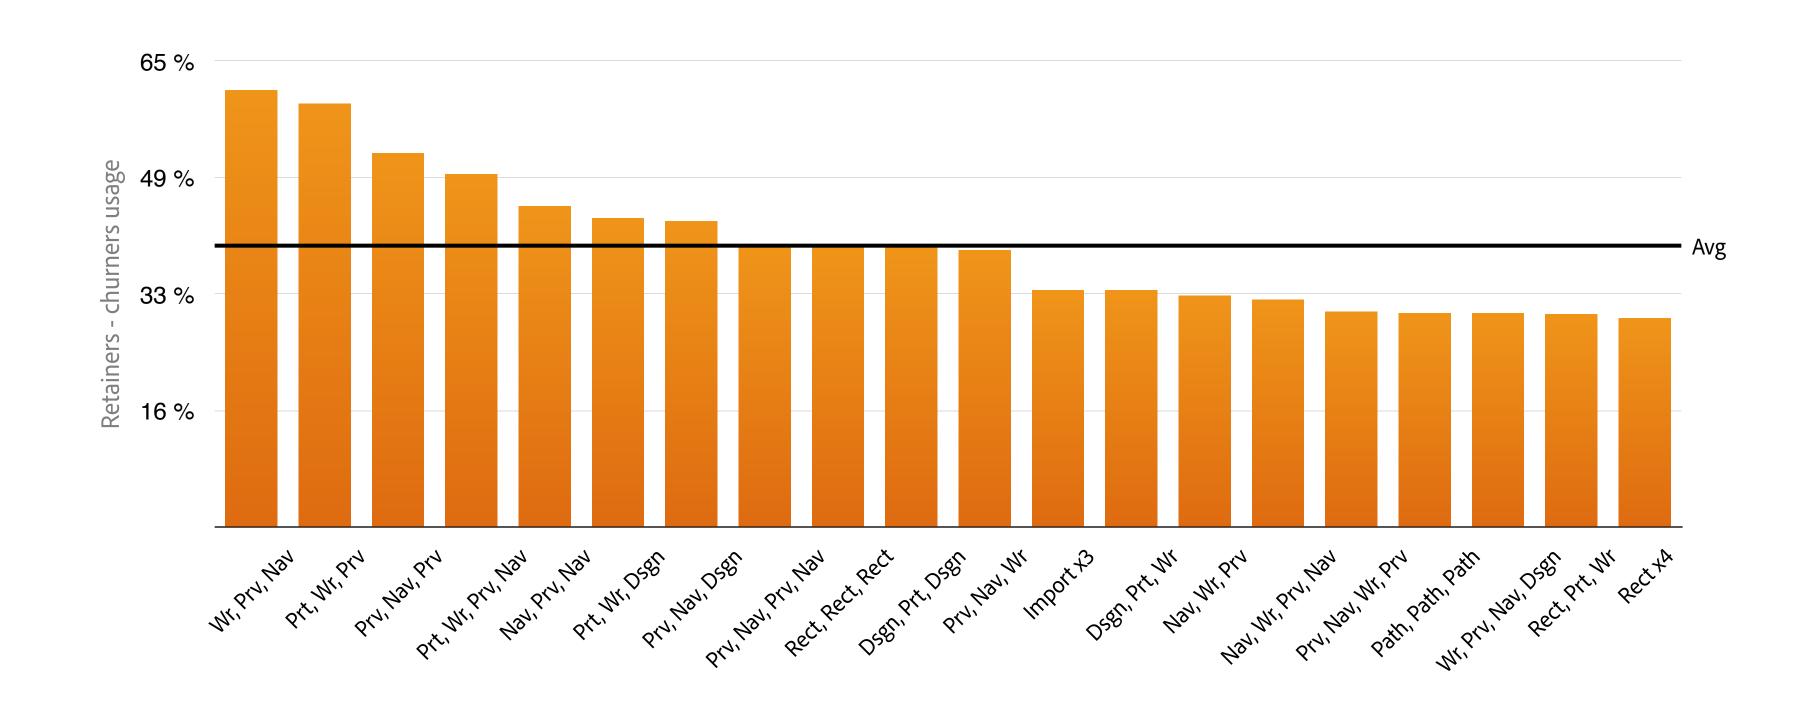

FS TECHNIQUES

- recursive feature elimination
- data analysis
- statistical methods

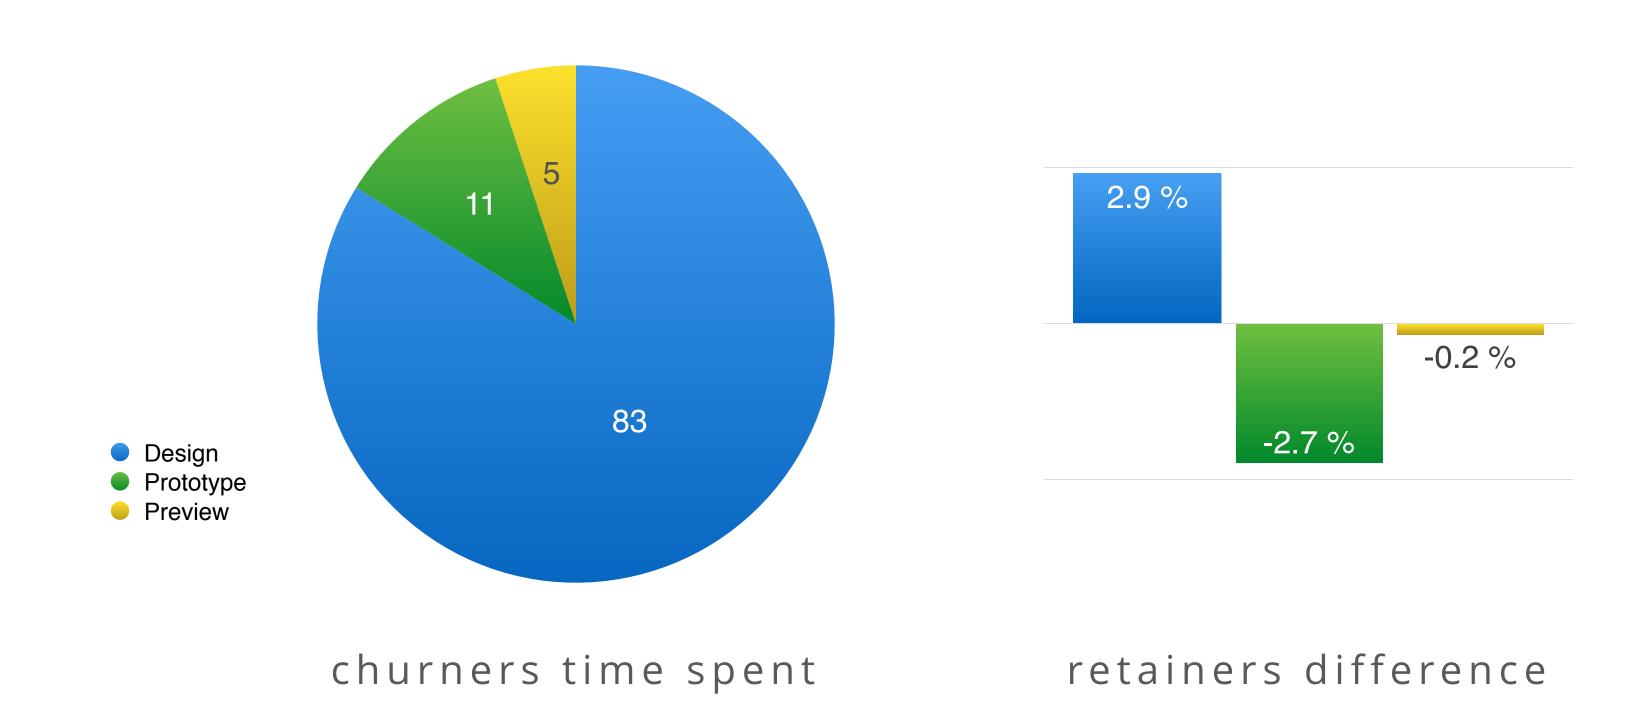

AVERAGE USAGE

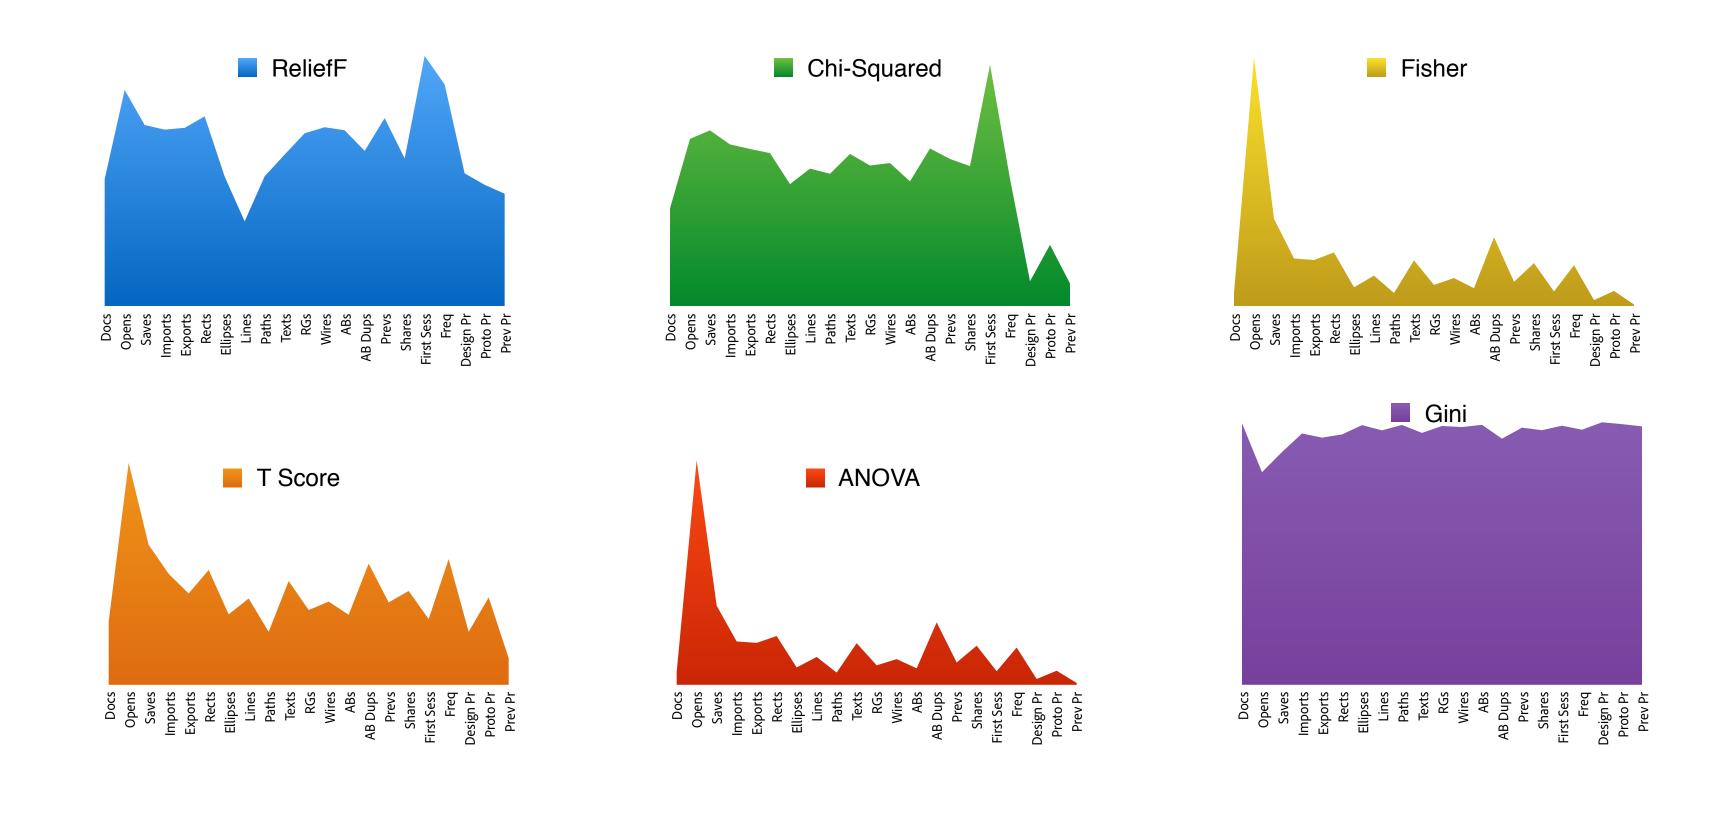

ACTION SEQUENCES

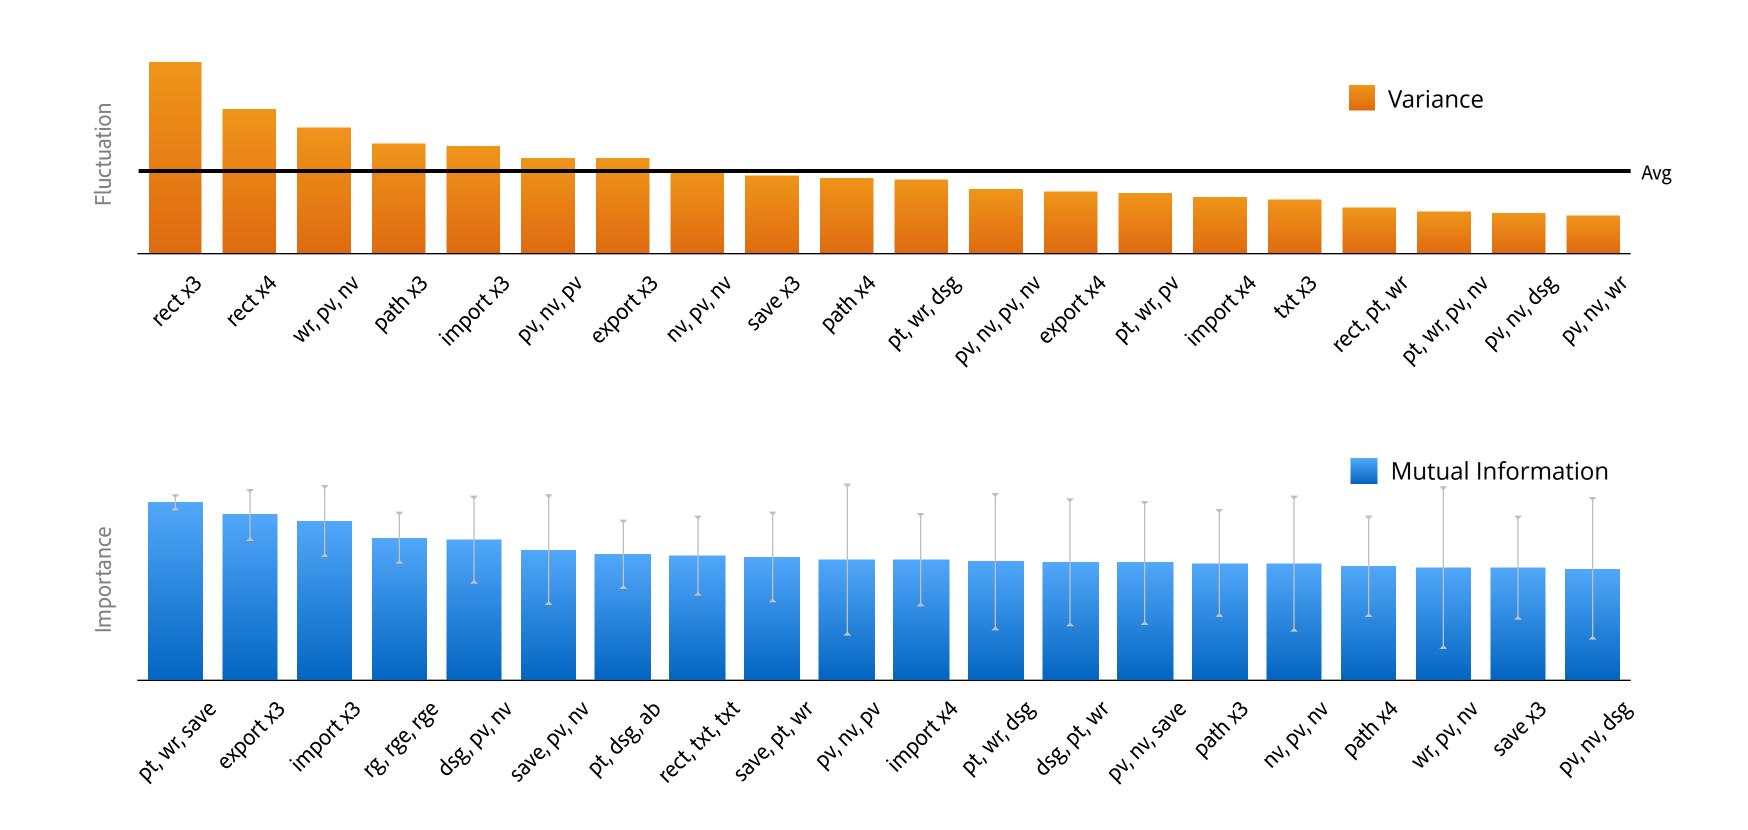

MODE PREFERENCE

STATISTICAL SCORES

STATISTICAL METHODS

MODEL OPTIMIZATION

PIPELINE

- gives the best model for a learning task
- seeks to minimize human input
- compensates for lack of experience

MODEL OPTIMIZATION

BEFORE

- Pick applicable learning methods on the task
 Select concrete learning **algorithms** for each method
- 2 Consider impactful hyper-parameters for each algorithm Pick sensible **ranges of values** for each hyper-parameter
- Run data analysis and statistical methods
 Propose most impactful feature subsets
- 4 Decide the desired **duration** allowed for optimization

MODEL OPTIMIZATION

STEPS

- Run exhaustive search on hyper-parameter grid on a **sample Restrict** hyper-parameters iterations and RFE step size based on time
- 2 Fit **hyper-parameters** for each model Using random-search (restricted)
- Chose best **feature subset** for each model

 Try the whole dataset, proposed subsets and RFE (restricted)
- Take best models (with diversity in mind)
 Use them as deciders for the **combining classifier**

META CLASSIFIER

classify based on the output of other algorithms, not on examples themselves

- learn **how** to learn
- already trained many models
- learn how to best combine their decisions

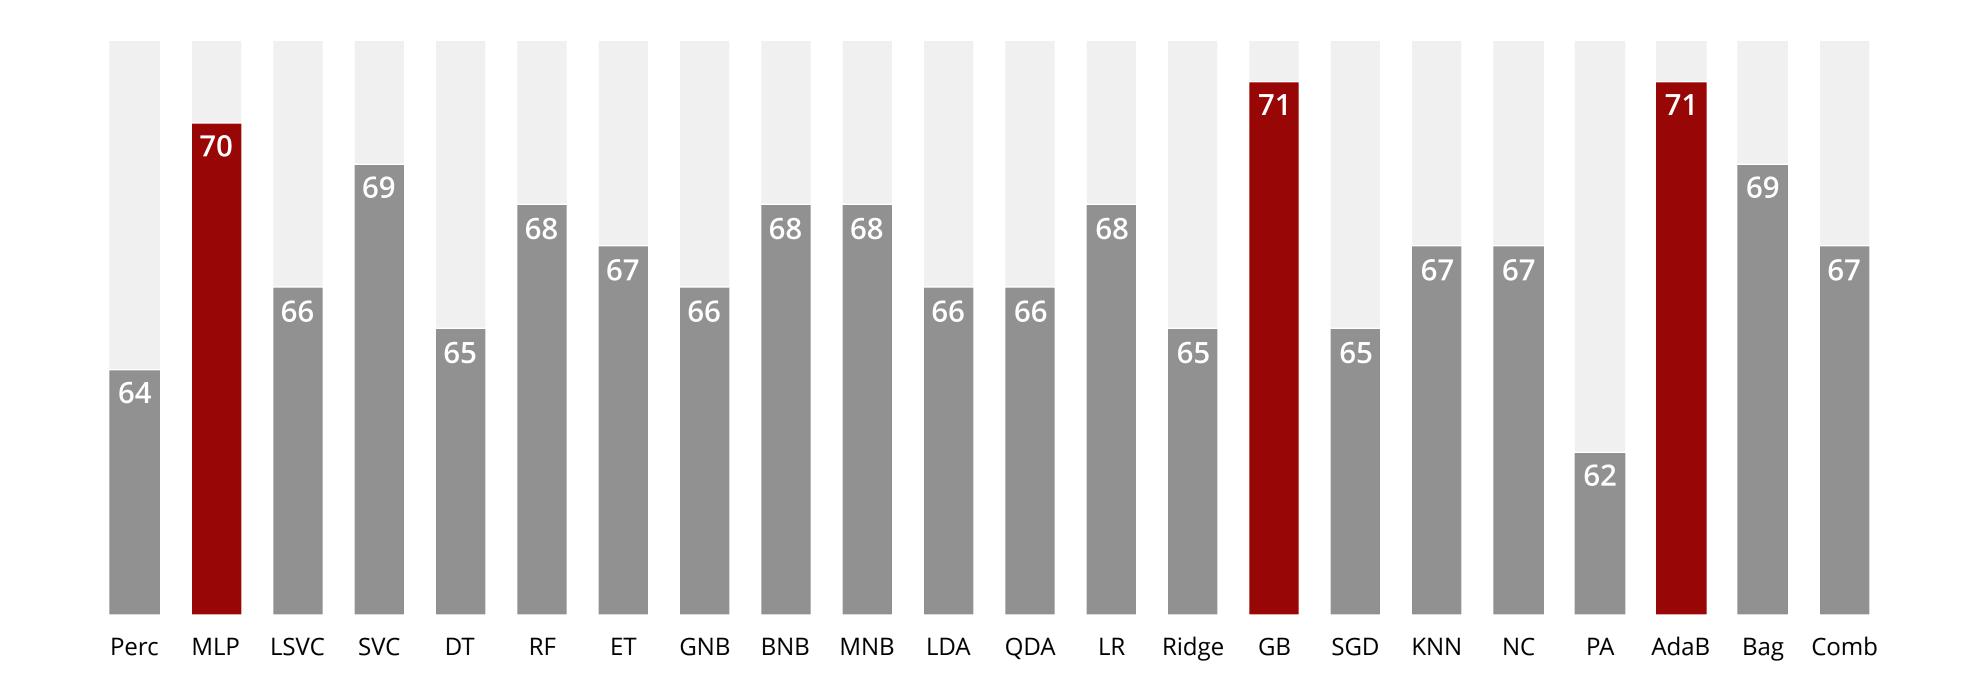

COMBINER

simple model for aggregating: shallow NN, small RF, linear SVM

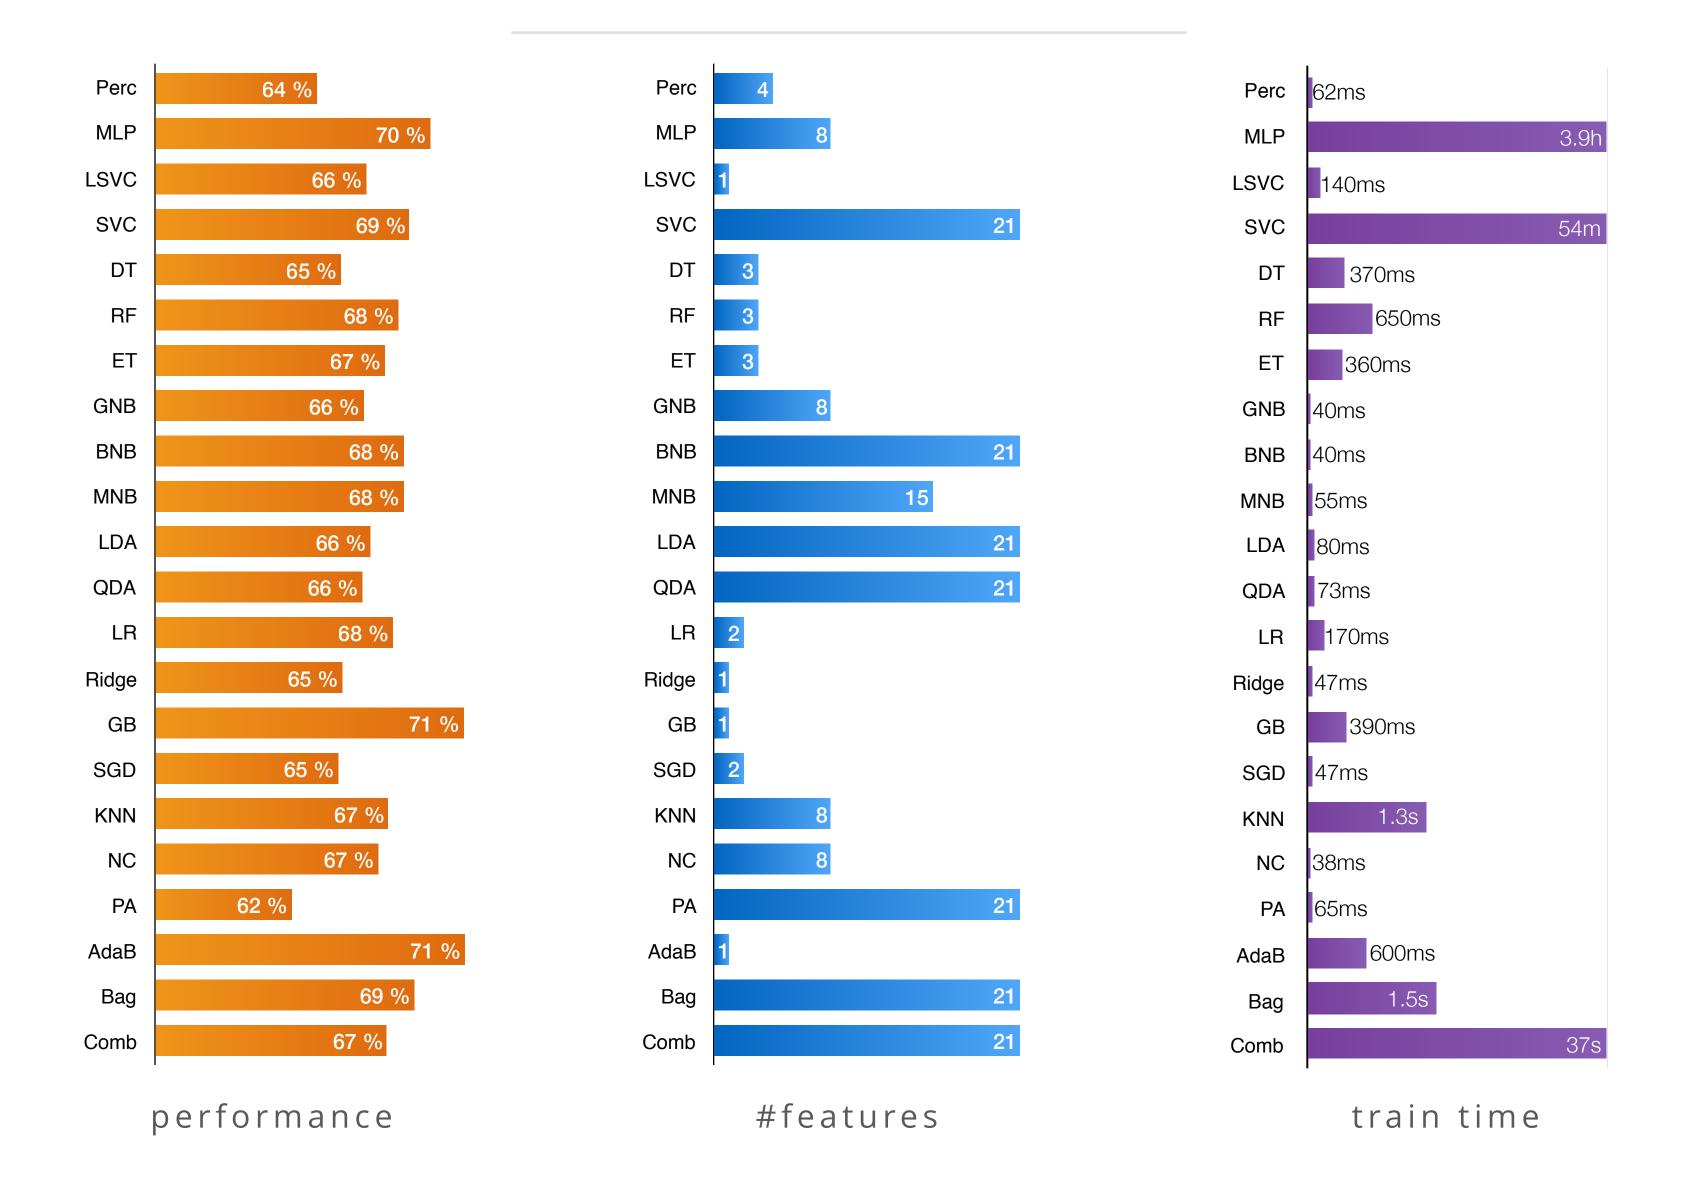

DECIDERS

take best performing models.
each has strengths and weaknesses,
compensate by promoting diversity

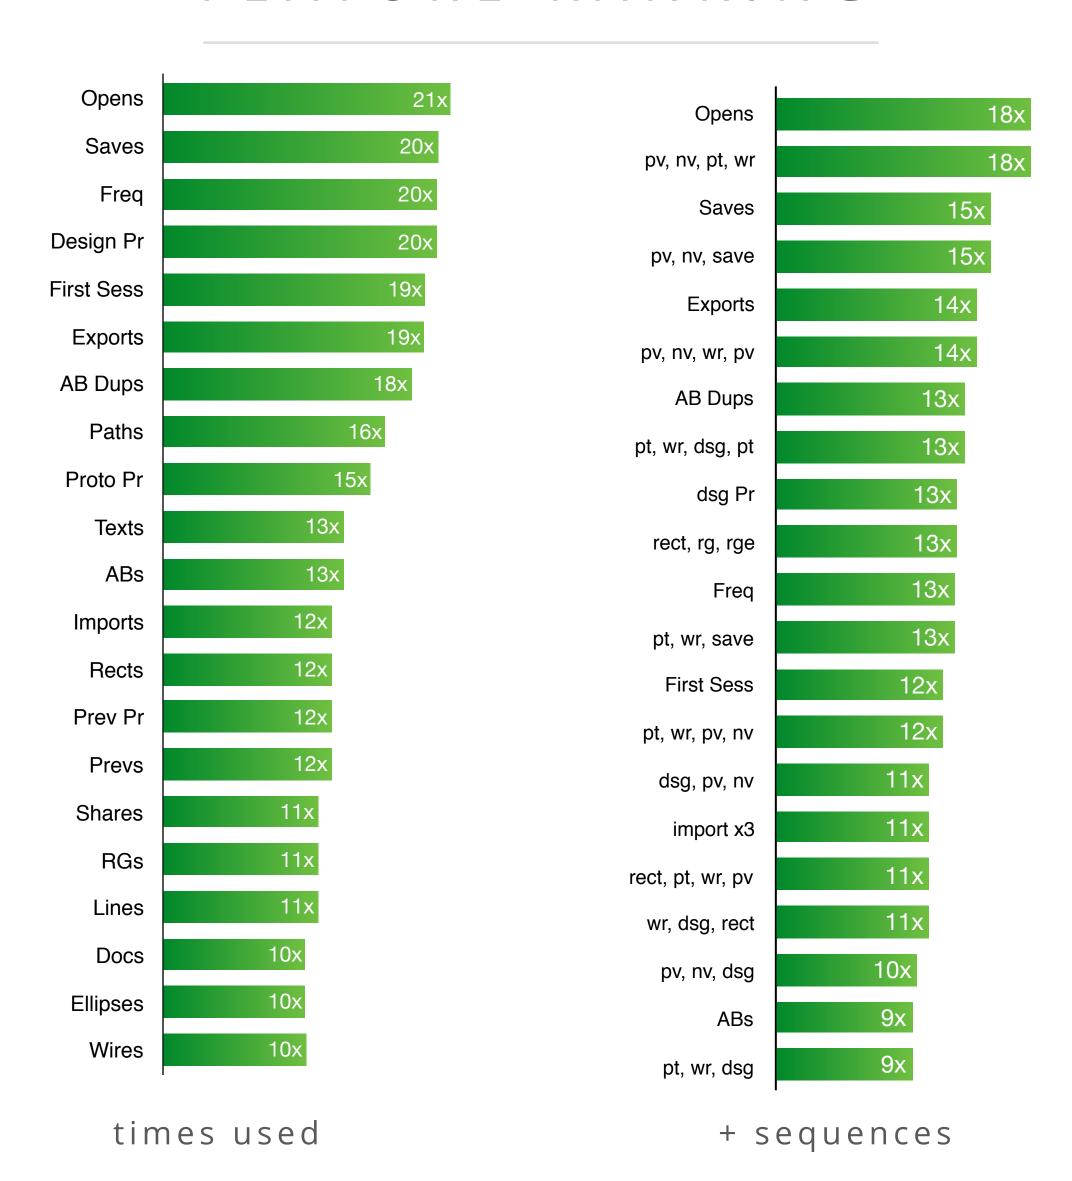

MODEL PERFORMANCE

MODEL COMPARISON

FEATURE RANKING

CONCLUSION

Important features:

- prototype, preview
- RGs, ABs

Field contribution:

- model optimization pipeline,
- combining classifier

NEXT STEPS

Technique refinement:

- continuous classification
- deep learning
- word embedding visualization

New direction:

- sequence learning
- predictive system
